What is elliptic cohomology?

**Definition 1.** For a ring $R$, an $R$-valued genus on a class of closed manifolds is a function $\varphi$ that assigns to each manifold $M$ an element $\varphi(M) \in R$ such that

(i) $\varphi(M_1 \coprod M_2) = \varphi(M_1) + \varphi(M_2)$
(ii) $\varphi(M_1 \times M_2) = \varphi(M_1) \varphi(M_2)$
(iii) $\varphi(M) = 0$ if $M$ is a boundary.

Equivalently, $\varphi$ is a homomorphism from the appropriate cobordism ring $\Omega$ to $R$.

**Definition 2.** A 1-dimensional formal group law over $R$ is a power series $F(x, y) \in R[[x, y]]$ satisfying

(i) $F(x, 0) = F(0, x) = x$.
(ii) $F(y, x) = F(x, y)$
(iii) $F(x, F(y, z)) = F(F(x, y), z)$.

A theorem of Quillen says that in the complex case (where $\Omega = MU_*$, the complex cobordism ring), $\varphi$ is equivalent to a 1-dimensional formal group law over $R$.

More precisely, there is a 1-dimensional formal group law $G$ over $MU_*$ having a certain universal property. It is defined as follows.

Let $\alpha$ be a complex line bundle over a space $X$. It has a Conner-Floyd Chern class $c_1(\alpha) \in MU^2(X)$. Given two such line bundles $\alpha_1$ and $\alpha_2$, we have

$$c_1(\alpha_1 \otimes \alpha_2) = G(c_1(\alpha_1), c_1(\alpha_2))$$

where $G$ is the desired formal group law.

This formal group law $G$ over $MU_*$ has the following universal property: Any formal group law $F$ over a ring $R$ is induced from $G$ via a homomorphism

$$\theta : MU_* \to R.$$ 

It follows that an $R$-valued genus on complex manifolds is equivalent to a 1-dimensional formal group law over $R$.

It is also known that the functor

$$X \mapsto MU_*(X) \otimes_\varphi R$$

is a homology theory if $\varphi$ satisfies certain conditions spelled out in Landweber’s Exact Functor Theorem.
Now suppose $E$ is an elliptic curve defined over $R$. It is a 1-dimensional algebraic group, and choosing a local parameter at the identity leads to a formal group law $\hat{E}$, the formal completion of $E$. Thus we can apply the machinery above and get an $R$-valued genus.

For example, the *Jacobi quartic*, defined by the equation
\[ y^2 = 1 - 2\delta x^2 + \epsilon x^4, \]
is an elliptic curve over the ring
\[ R = \mathbb{Z}[1/2, \delta, \epsilon]. \]

The resulting formal group law is the power series expansion of
\[ F(x, y) = \frac{x\sqrt{1 - 2\delta y^2 + \epsilon y^4} + y\sqrt{1 - 2\delta x^2 + \epsilon x^4}}{1 - \epsilon x^2 y^2}, \]
this calculation is originally due to Euler. The resulting genus is known to satisfy Landweber’s conditions, and this leads to one definition of elliptic cohomology.
What are modular forms?

Recall that an elliptic curve is determined by a lattice in $\mathbb{C}$ generated by 1 and a complex number $\tau$ in the upper half plane $H$. There is an action of the group $SL_2(\mathbb{Z})$ on $H$ given by

$$\tau \mapsto \tau' = \frac{a\tau + b}{c\tau + d} \text{ for } \begin{bmatrix} a & b \\ c & d \end{bmatrix} \in SL_2(\mathbb{Z}).$$

An easy calculation shows that $\tau'$ determines the same lattice as $\tau$. This means that elliptic curves are parametrized by the orbits under this action.

A modular form of weight $k$ is a meromorphic function $g$ defined on the upper half plane satisfying

$$g\left(\frac{a\tau + b}{c\tau + d}\right) = (c\tau + d)^k g(\tau).$$

Here is an example. Let

$$G_k(\tau) := \sum_{m,n\in\mathbb{Z}}' \frac{1}{(m\tau + n)^k}$$

where the sum is over all nonzero lattice points. This vanishes if $k$ is odd and is known to converge for $k > 2$.

Note that

$$G_k\left(\frac{a\tau + b}{c\tau + d}\right) = \sum_{m,n\in\mathbb{Z}}' \left(\frac{c\tau + d}{m(a\tau + b) + n(c\tau + d)}\right)^k = (c\tau + d)^k G_k(\tau).$$

so $G_k$ is a modular form of weight $k$. 
Now let $q = e^{2\pi i \tau}$. In terms of it we have
\[ G_k(\tau) = 2(2\pi i)^k \frac{B_k}{2k!} \left( 1 - \frac{1}{B_k} \sum_{n=1}^{\infty} \sigma_{k-1}(n)q^n \right) \]
where $B_k$ is the $k$th Bernoulli number defined by
\[ \frac{x}{e^x - 1} =: \sum_{k \geq 0} B_k \frac{x^k}{k!}, \]
and
\[ \sigma_{k-1}(n) := \sum_{d | n} d^{k-1}. \]

It is convenient to normalize $G_k$ by defining the Eisenstein series
\[ E_k(\tau) := 1 - \frac{2k}{B_k} \sum_{n=1}^{\infty} \sigma_{k-1}(n)q^n. \]

It turns out that
\[ E_k(\tau) = \sum_{(m,n)=1} \frac{1}{(m\tau+n)^k}, \]
where the sum is over pairs of integers that are relatively prime.

Let
\[ \Delta := \frac{E_4(\tau)^3 - E_6(\tau)^2}{1728} = q \prod_{n=1}^{\infty} (1 - q^n)^{24} \]
and
\[ j := \frac{E_4^3}{\Delta}. \]

$\Delta$ is called the discriminant, and the modular function $j$ of weight 0 is a complex analytic isomorphism between $H/SL_2(\mathbb{Z})$ and the Riemann sphere.

It is known that the ring of all modular forms with respect to $\Gamma = SL_2(\mathbb{Z})$ is
\[ M_*(\Gamma) = \mathbb{C}[E_4, E_6], \]
with $(\Delta)$ being the ideal of forms that vanish at $i\infty$, which are called cusp forms.
The Weierstrass Curve

The *Weierstrass equation* for an elliptic curve in affine form is

\[ y^2 + a_1 xy + a_3 y = x^3 + a_2 x^2 + a_4 x + a_6. \]

It is known that any elliptic curve is isomorphic to one of this form.

The Eisenstein series are related to the \( a_k \) by

\[ E_4 = b_2^2 - 24b_4 \]

and

\[ E_6 = -b_2^3 + 36b_2b_4 - 216b_6 \]

where

\[
\begin{align*}
b_2 &= a_1^2 + 4a_2 \\
b_4 &= a_1a_3 + 2a_4 \\
b_6 &= a_3^2 + 4a_6.
\end{align*}
\]

Then

\[ \Delta = \frac{E_4^3 - E_6^2}{1728} \]

is the discriminant of the Weierstrass equation, meaning that the curve is smooth iff \( \Delta \) is a unit in the ground ring. 2

This means there is a formal group law defined over the ring

\[ \mathbb{E}_\ell \mathbb{L} = \mathbb{Z}[a_1, a_2, a_3, a_4, a_6][\Delta^{-1}] \]

and the resulting genus is Landweber exact.

Thus we get a spectrum \( \mathbb{E}_\ell \mathbb{L} \) with \( \pi_*(\mathbb{E}_\ell \mathbb{L}) = \mathbb{E}_\ell \mathbb{L} \).

Consider the affine coordinate change

\[ y \mapsto y + r \quad \text{and} \quad x \mapsto x + sy + t \]

It can be thought of as an action of an affine group \( G \) of \( 3 \times 3 \) matrices given by

\[
\begin{bmatrix}
1 & s & t \\
0 & 1 & r \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
x \\
y \\
1
\end{bmatrix}
= \begin{bmatrix}
x + sy + t \\
y + r \\
1
\end{bmatrix}
\]

Under it we get

\[
\begin{align*}
a_6 &\mapsto a_6 + a_4 r + a_3 t + a_2 r^2 \\
&\quad + a_1 r t + t^2 - r^3 \\
a_4 &\mapsto a_4 + a_3 s + 2a_2 r \\
&\quad + a_1 (r s + t) + 2 s t - 3 r^2 \\
a_3 &\mapsto a_3 + a_1 r + 2 t \\
a_2 &\mapsto a_2 + a_1 s - 3 r + s^2 \\
a_1 &\mapsto a_1 + 2 s.
\end{align*}
\]
The spectrum $tmf$

Very roughly speaking, there is an action of the group $G$ on the spectrum $E\ell$ inducing the above action on its homotopy groups.

The homotopy fixed point set of this action is $tmf$.

There is a spectral sequence converging to $\pi_*(tmf)$ with

$$E_2 = H^*(G; E\ell_*)$$

The modular forms $E_4$ and $E_6$ are both invariant under this action, and

$$H^0(G; E\ell_*) = \mathbb{Z}[E_4, E_6][\Delta^{-1}]$$

The coordinate change above can be used to define a Hopf algebroid $(A, \Gamma)$ with

\[
\begin{align*}
A &= \mathbb{Z}[a_1, a_2, a_3, a_4, a_6] \\
\Gamma &= A[r, s, t]
\end{align*}
\]

and right unit $\eta_R : A \to \Gamma$ given by the formulas above.

This was first described by Hopkins and Mahowald in *From elliptic curves to homotopy theory*. Its Ext group is the cohomology group mentioned above. Tilman Bauer has written a nice account of this calculation.
