$$\mathcal{M} \begin{array}{c} \xrightarrow{F} \\ \perp \\ \xleftarrow{U} \end{array} \mathcal{N}$$

be a transfer adjunction as above. Then there is a cofibrantly generated model structure on \mathcal{N} (the **transferred model structure**), for which \mathcal{FI} and \mathcal{FJ} are cofibrant generating sets, and the weak equivalences and fibrations are the maps taken by U to weak equivalences and fibrations in \mathcal{M} . Furthermore, with respect to this model structure, (F, U) is a Quillen pair.

This is our main tool for constructing new model structures. Note that \mathcal{N} does not have a model structure to begin with.

Back to functor categories (continued)

Consider the adjunction

$$\mathcal{M}^K \begin{array}{c} \xrightarrow{\alpha_!} \\ \perp \\ \xleftarrow{\alpha^*} \end{array} \mathcal{M}^J.$$

In terms of the projective model structure on \mathcal{M}^K , this is a transfer adjunction. For a functor X in \mathcal{M}^K , we have

$$(\alpha_! X)_j = \begin{cases} X_j & \text{for } j \in \text{Im } \alpha \\ * & \text{otherwise} \end{cases}$$

The Crans-Kan transfer theorem gives us an induced model structure on \mathcal{M}^J which differs from the projective one.

Stabilization

More about stabilization (continued)

In general there are two ways to describe Bousfield localization. In the case of orthogonal G -spectra we can do both.

- 1 For each representation V , we define a **stabilizing map** $s_V : S^{-V} \wedge S^V \rightarrow S^{-0}$ as follows. Its W th component is the composition morphism

$$\begin{array}{ccc} (S^{-V} \wedge S^V)_W & & (S^{-0})_W \\ \parallel & & \parallel \\ \mathcal{I}_G(V, W) \wedge \mathcal{I}_G(0, V) & \xrightarrow{j_{0, V, W}} & \mathcal{I}_G(0, W). \end{array}$$

For $V \neq 0$ this map is a stable equivalence but not a projective one.

- 2 To define the fibrant replacement RX of a spectrum X ,
